# Artificial Neural Network Approach as an Alternative to Ridge Regression on an Economic Problem

SENAY YOLACAN, BERNA YAZICI, EMBIYA AGAOGLU Department of Statistics Anadolu University Eskisehir, 26470 TURKEY

*Abstract:* In this study ridge regression and artificial neural network (ANN) algorithm that does not require any assumption are applied on an economic data set with multicollinearity. The results are interpreted and compared.

Key-Words: Ridge regression, multicollinearity, artificial neural networks.

### **1** Introduction

The least squares estimators of the regression coefficients are the best linear unbiased estimators. That is, of all possible estimators that are both linear functions of the data and unbiased for the parameters being estimated, the least squares estimators have the smallest variance.

One of the assumptions of linear regression model is the independency of explanatory variables. If those variables are correlated with each other multicollinearity problem occurs. Multicollinearity is defined as the existence of nearly linear dependency among column vectors of the design matrix X in the linear model  $Y = X\beta + u$ . One way of explaining the structure of multicollinearity is to look over the eigenvalues and eigenvectors of the matrix XX. One or more small eigenvalues show the existence of multicollinearity (Akdeniz and Erol, 2003).

In the presence of multicollinearity minimum variance may be unacceptably large. Severe multicolinearity makes the estimates so unstable that they are practically useless and the matrix XX becomes singular. To overcome this problem there are several biased estimation methods proposed by different authors including ridge regression (Hoerl and Kennard, 1970), Liu estimator (Liu, 1993).

In this study firstly ridge regression among biased estimation methods is taken into account, afterwards appropriate ANN algorithm is defined. The advantages and disadvantages of using that algorithm are mentioned. An application study is given about economical indicators. The last part of the study the conclusions and recommendations are given.

## 2 Ridge Regression

Ridge regression is a popular method for dealing with multicollinearity builds on the fact that a singular square matrix can be made nonsingular by adding a constant to the diagonal of the matrix. The model is as in Eq.1.

$$\hat{\beta} = (Z'Z + kI)^{-1}Z'Y$$
(1)

Where k is called shrinkage parameter, I is the identity matrix. Z is the standardized design matrix using following standardization:

$$\mathbf{Z} = \frac{X_{ij} - \overline{X}_{j}}{\sqrt{\sum \left(X_{ij} - \overline{X}_{j}\right)^{2}}}$$
(2)

k changes between 0 and 1 and the estimation of the parameters change with the value of k. When k=0 we have the ordinary least squares estimator of  $\hat{\beta}$  of  $\beta$ . The goal is to choose k so as to minimize the mean squared error (MSE). However, MSE cannot be evaluated and therefore the choice of k is somewhat subjective. In order to overcome this problem an ANN algorithm is used to estimate regression parameter.

#### **3 Radial Basis Functions Network**

Optimal ridge regression parameters can be estimated for linear feed forward networks in supervised learning problems. With radial basis functions (RBF) because of their local nature ridge regression with multiple adjustable regularization parameters performs a kind of locally adaptive smoothing. The optimization is performed using either unbiased estimate of variance or generalized cross validation and needs an initial guess for the values of the parameters. Parameters in both the initial guesses and the final optimal estimates whose value is infinity correspond to pruned basis functions (Orr, 1997).

RBF networks have traditionally been associated with radial functions in a single-layer network as shown in Figure 1. The input layer is made of source nodes that connect the network to its environment. The second layer, the only hidden layer in the network, applies a non-linear transformation from the input space to the hidden space; one important point is the fact that the dimension of the hidden space is directly related to the capacity of the network to approximate a smooth input-output mapping (in most applications the hidden space is of high dimensionality). The output layer is linear, supplying the response of the network to the activation pattern applied to the input layer.

Figure 1. The traditional radial basis function network. Each of n components of the input vector x feeds forward to m basis functions whose outputs are linearly combined with weights  $\{w_j\}_{j=1}^m$  into the network output f(x).

A RBF network, therefore, has a hidden layer of radial units, each actually modeling a Gaussian response surface. Since these functions are nonlinear, it is not actually necessary to have more than one hidden layer to model any shape of function: sufficient radial units will always be enough to model any function. (Haykin, 1999; Bishop, 1995)

In standard ridge regression for smoothing linear networks the cost function is made up of the usual sum-squared error plus a roughness penalty dependent on the squared length of the weight vector and a positive regularization parameter, k:

$$C(w,k) = \sum_{i=1}^{p} (f(x_i, w) - y_i)^2 + k \sum_{j=1}^{m} w_j^2 \qquad (3)$$

where  $f(x) = \sum_{j=1}^{m} w_j h_j(x)$  is the output of the

network for input x and weight vector w and  $\{(x_i, y_i)\}_{i=1}^p$  is the training set. A generalization of this to the case of multiple regularization parameters,  $k = [k_1 k_2 \dots k_m]^T$  (one for each basis function) is

$$C(w,k) = \sum_{i=1}^{p} \left( f(x_i, w) - y_i \right)^2 + \sum_{j=1}^{m} k_j w_j^2 \qquad (4)$$

In the case of least squares applied to supervised learning with a linear model the function to be minimized is the cost function given in Eq. (4) used in ridge regression. Optimal weight vector is found as a result of this minimization as follows:

$$\hat{w} = \left(H^T H + kI_m\right)^{-1} H^T \hat{y}$$
<sup>(5)</sup>

where H is design matrix, has the vectors  ${h_j}_{j=1}^m$  as its columns, and has p rows, one for each pattern in the training set.

An important point is that if the training set has been used to estimate the regularization parameter(s), as in ridge regression, or to chose the basis functions, as in forward selection, the  $(H^T H + kI_m) = A$  is a stochastic variable and there is no longer a simple linear relationship between uncertainty in  $\hat{w}$  and uncertainty in  $\hat{y}$  (Orr, 1997).

Moreover RBF network has advantages: first, when we choose the ridge parameter k, we are able to choose a small number which is much more effective for smoothing the data. Further, by having the single parameter for adjusting the payoff between the two factors we can choose k appropriately so that we may vary any potential solution between the extremes of RBF and canonical correlation analysis depends on the needs of any particular data set (Gou and Fyfe, 2003).

### **4** Application

In this part of the study a data set on Turkey's GDP between 1988 and 2004 is analyzed both using ridge regression and ANN. The variables of the model are as follows:

Y: GDP deflator

- X<sub>1</sub>: Money Supply
- X<sub>2</sub>: Money Supply (previous term)
- X<sub>3</sub>: Inflation rate
- X<sub>4</sub>: Exchange rate
- X<sub>5</sub>: Unemployment Rate

X<sub>6</sub>: Harmonized Indices of Consumer Prices (HCIP %)

- X<sub>7</sub>: Interest Rate
- X<sub>8</sub>: volume of currency issued

X<sub>9</sub>: Gross Domestic Product (% increase)

Ridge regression parameters are estimated for different k values. The estimates are given in Table 1. The standard errors of parameter estimates are given in Table 2.

Table 1. Ridge estimates for different k values.

Figure 2. Ridge trace for Turkey's GDP data

k is chosen taken account the ridge trace given in Figure 2. k is defined as 0.3. Ridge estimates and related mean absolute error (MAE) value are given in Table 4.

Table 3. The weights of RBFN for Turkey's GDP data

	55.8	68.22	55.80				
	50.9	52.67	57.95				
	55.3	55.76	55.97				
	44.4	35.82	44.40				
	22.5	20.85	31.36				
<u> </u>	11.9	24.48	11.90				
MAE(Ridge)=4.91							
MAE(RBF	F) = 2.28						

As can be seen in Table 4 the MAE value for RBFN is quite small than the MAE value for ridge regression.

#### **5** Conclusions and Recommendations

Multicollinearity is a very common problem in multiple linear regression. Ridge regression is one of the biased methods that are used in order to overcome that problem. But choosing k in ridge regression is somewhat subjective. Hence in this study one of the algorithms of ANN, RBFN is used.

As a criterion of comparison MAE for each model is calculated. It is seen that the RBFN result is better than ridge regression result.

Another advantage of using RBFN is the researcher does not need to define a k value to make the best estimation.

For the further studies also Liu estimators can be used and all results can be compared using MAE values.
