Abstract:
Reliability Models based on Markov Chains (except Queuing models) have extensive application in reliability of electrical and electronically equipments. In this article, a system with two parallel and identical elements with increasable failure rate is analyzed and the results are in consideration of failure rates in of triangular fuzzy numbers. Also, to reach a triangular fuzzy number related to failure rate the $\beta^{-1}$ confidence interval of increasable failure rate is used. ($\lambda$ of raily distribution).

1) Introduction:
Nowadays, Reliability models are considered one of the most important applications of Markov Chains, and most electronic systems come across these models. This is an extensive system and for every electrical system a specific model is designed and implemented and in these models Failure Rate is definite. Since these failure rates are driven from gathering data and usage of probability distribution functions, or the opinions of the experts on the matter, uncertainty is also, an obvious parameter. Hence, in this article, one particular system with two parallel elements is reviewed and the results are in consideration of increasable failure rate ($\lambda t$).

To demonstrate the uncertainty in calculation of failure rate, these parameters are estimated through a triangular fuzzy number and to calculate the parameters of this fuzzy number, the $\% (1 - \beta)$ confidence interval [1] of this parameter witch is driven in respect to $\chi^2$ p.d.f is used. Therefore, by solving one numeric sample while all the system elements are identical, comparing the driven results with the crisp model results indicates a more realistic and practical result than crisp condition.

2) Notifications:
The notification that used in this article is as followed:

$\lambda_i$ : Failure rate of $i$ element.
$L_i$ : Lower limit of triangular fuzzy number related to failure rate of $i$ element.
$M_i$ : Medium of triangular fuzzy number related to failure rate of $i$ element.
$U_i$ : Upper limit of triangular fuzzy number related to failure rate of $i$ element.
$P_i(t)$ : Probability of the system at the $t$ moment to be in condition $i$.
$R_i(t)$ : Probability of the functionality of the system.
$MTTF$ : Mean time to failure.

3) Introduction to the discussed sample:
In this article, a system working with two parallel elements is considered. Assuming that the system will stop working when both elements have malfunctioned, we can consider the following four conditions for the system:

<table>
<thead>
<tr>
<th>State</th>
<th>Condition of first part</th>
<th>Condition of second part</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Working</td>
<td>Working</td>
</tr>
<tr>
<td>2</td>
<td>Not working</td>
<td>Working</td>
</tr>
<tr>
<td>3</td>
<td>Working</td>
<td>Not working</td>
</tr>
<tr>
<td>4</td>
<td>Not working</td>
<td>Not working</td>
</tr>
</tbody>
</table>

Table 1 : States of the system

and the flow diagram for this system will be as follow:
in respect to the above descriptions, the probability of the system functioning is calculated as followed
\[ R_p(t) = P_1(t) + P_2(t) + P_3(t) \]  \hspace{1cm} (01)

We also know that:
\[ P_1(t) + P_2(t) + P_3(t) + P_4(t) = 1 \]  \hspace{1cm} (02)

In this system, the purpose is to find \( P_i(t), i = 1, 2, 3 \). For the loads 1 through 3 in figure 1 we have:
\[ P_1(t + \Delta t) = P_1(t) - \lambda_1 \Delta t P_1(t) - \lambda_2 \Delta t P_2(t) \]  \hspace{1cm} (03)
\[ P_2(t + \Delta t) = P_2(t) + \lambda_1 \Delta t P_1(t) - \lambda_2 \Delta t P_2(t) \]  \hspace{1cm} (04)
\[ P_3(t + \Delta t) = P_3(t) + \lambda_2 \Delta t P_2(t) - \lambda_1 \Delta t P_1(t) \]  \hspace{1cm} (05)

and by solving the equations (03) through (05) we can calculate the values \( P_i(t), i = 1, 2, 3 \) as followed:
\[ P_1(t) = e^{-\frac{1}{2}[(\lambda_1 + \lambda_2)t]} \]  \hspace{1cm} (06)
\[ P_2(t) = e^{-\frac{1}{2}[(\lambda_1 + \lambda_2)t]} - e^{-\frac{1}{2}[(\lambda_1 + \lambda_2)t]} \]  \hspace{1cm} (07)
\[ P_3(t) = e^{-\frac{1}{2}[(\lambda_1 + \lambda_2)t]} - e^{-\frac{1}{2}[(\lambda_1 + \lambda_2)t]} \]  \hspace{1cm} (08)

and the system **MTTFS** is also calculated as followed:
\[ MTTFS = \frac{\infty}{0} R_p(t) dt = \frac{2\pi}{\lambda_1} + \frac{2\pi}{\lambda_2} + \frac{2\pi}{(\lambda_1 + \lambda_2)} \]  \hspace{1cm} (09)

4) Calculations with respect to Fuzzy failure Rates:
Most important consideration is that the Values of \( \lambda_i, i = 1, 2 \) are not fixed. Since they are driven from collected data or the opinions of the experts, uncertainty of the value is an undeniable fact.
Most of the times, these failure rates considered as a known value or have a known distributions function.
In this article we assume that the failure rates have raily p.d.f. Of course in this condition, failure rates, \( \lambda_i, i = 1, 2 \) is considered in the form of a Triangular Fuzzy Number as follows:
\[ \overline{\lambda}_i = \left( L_i, M_i, U_i \right) \quad i = 1, 2 \]  \hspace{1cm} (10)

In which \( L_i \) are the Lower Limits of \%(1 - \beta) confidence interval, \( M_i \) are the Point estimations, and \( U_i \) are the upper limits of \%(1 - \beta) confidence interval of \( \lambda_i \).
The \( \alpha \)-cut of these failure rates can be calculated as follow:
\[ \overline{\lambda}_i[\alpha] = [L_i + \alpha(M_i - L_i), U_i - \alpha(U_i - M_i)] \quad i = 1, 2 \]  \hspace{1cm} (11)

Now we can calculate the \( P_i(t), i = 1, 2, 3 \) in Fuzzy condition by using extension principle [2].
Assume \( \overline{P}_i[\alpha] = [P_1[\alpha], P_2[\alpha], P_3[\alpha]], i = 1, 2, 3 \) therefore we will have [3]:
\[ \overline{P}_1[\alpha] = [P_1[\alpha], P_2[\alpha], P_3[\alpha]] \]  \hspace{1cm} (12)
\[ P_1[\alpha] = e^{-\frac{1}{2}[(\lambda_1 + \lambda_2)[\alpha]t]} \]  \hspace{1cm} (13)
\[ P_2[\alpha] = e^{-\frac{1}{2}[(\lambda_1 + \lambda_2)[\alpha]t]} - e^{-\frac{1}{2}[(\lambda_1 + \lambda_2)[\alpha]t]} \]  \hspace{1cm} (14)
\[ P_3[\alpha] = e^{-\frac{1}{2}[(\lambda_1 + \lambda_2)[\alpha]t]} - e^{-\frac{1}{2}[(\lambda_1 + \lambda_2)[\alpha]t]} \]  \hspace{1cm} (15)

**Fig 1:** States of the system
\[ R_{p}(t, \alpha) = \begin{cases} R_{P_1}(t, \alpha), & \text{if } R_{P_1}(t, \alpha) \\
R_{P_2}(t, \alpha), & \text{if } R_{P_2}(t, \alpha) \end{cases} \]

\[ R_{P_1}(t, \alpha) = \frac{1}{2\pi} \int \frac{1}{\sqrt{U_1 + U_2}} e^{-\frac{1}{2} \left( \frac{(U_1 - M_1)^2}{U_1} + \frac{(U_2 - M_2)^2}{U_2} \right)} \, dx \]

(15)

\[ R_{P_2}(t, \alpha) = \frac{1}{2\pi} \int \frac{1}{\sqrt{U_1 + U_2}} e^{-\frac{1}{2} \left( \frac{(U_1 - M_1)^2}{U_1} + \frac{(U_2 - M_2)^2}{U_2} \right)} \, dx \]

Assume \( \overline{MTTF}_1(\alpha) = [MTTF_1(\alpha), MTTF_2(\alpha)] \) therefore we will have:

\[ MTTF_1(\alpha) = \int_0^\infty R_{P_1}(t, \alpha) \, dt = \]

(16)

\[ MTTF_2(\alpha) = \int_0^\infty R_{P_2}(t, \alpha) \, dt = \]

(17)

and to calculate the Fuzzy Number related to the mean time to failure of system \( \overline{MTTF} \) we have:

\[ \overline{MTTF} = (A/B/C) \]

(18)

\[ A = MTTF_1(0) = (2\sqrt{2} + 1) \sqrt{\frac{\pi}{U}} - 2 \sqrt{\frac{\pi}{L}} \]

(19)

\[ B = MTTF_1(1) = MTTF_2(2) = (2\sqrt{2} - 1) \sqrt{\frac{\pi}{M}} \]

(20)

\[ C = MTTF_2(0) = (2\sqrt{2} + 1) \sqrt{\frac{\pi}{L}} - 2 \sqrt{\frac{\pi}{U}} \]

(21)

Now assuming that both elements are identical and because Fuzzy rates of these Elements have exponential distribution with unknown parameter \( \lambda \), the point estimation and \( 95\% \) confidence intervals (two ways) of this parameter are:

\[ M = \frac{1}{X^2} \]

(22)

\[ L = \frac{X_0.95^2 \lambda \lambda}{n \times X^2} \]

(23)

\[ U = \frac{X_0.05^2 \lambda \lambda}{n \times X^2} \]

(24)

In here

\[ \overline{X} = \frac{\sum_{i=1}^n X_i}{n} \]

(25)

Now, by plugging the driven values from equations (22) to (24) in equations (19) to (21) we will have:

\[ A = MTTF_1(0) = (2\sqrt{2} + 1) \left( \frac{\pi}{X^2} \right) - 2 \left( \frac{\pi}{X^2} \right) \]

(26)

\[ B = MTTF_1(1) = MTTF_2(2) = (2\sqrt{2} - 1) \left( \frac{\pi}{X^2} \right) \]

(27)

\[ C = MTTF_2(0) = (2\sqrt{2} + 1) \left( \frac{\pi}{X^2} \right) - 2 \left( \frac{\pi}{X^2} \right) \]

(28)

At the end, we defuzzy \( \overline{MTTF} \) and then we will have:

\[ \overline{MTTF} = (A/B/C) = \left( \frac{2\sqrt{2} - 1}{3} \right) \left( \frac{\pi}{X^2} \right) + \left( \frac{2\sqrt{2} - 1}{3} \right) \left( \frac{\pi}{X^2} \right) \]

(29)

5) Numeric Sample

Assumptions based on an independent example with volume \( n = 25 \), failure rate is estimated at \( X^2 = 920 \),
therefore $\overline{\tau} = 0.001087$. In the example in the crisp condition, the results are clocked at $MTTF = 98.2970$, in table 2.

</table>

Table 2: The value of A, B, C and the MTTF

Values of $MTTF$ are calculated and presented based on the values of $\beta$. Also in this table, where the values of the lower limits of the Fuzzy Triangular Number were negative (column A), they were replaced with 0, and where the values of the upper limit is lower than $B$, we replaced it with $B$.

6- Conclusion, and Further research

Since we can see in figure 2, the system did not works more stable than system function in the crisp condition, but, because of using fuzzy failure rates, the system condition is more realistically than crisp condition, and these are the advantages of this model.

The system discussed in this article is one of hundreds of the actual existing systems that have already been produced based on definite parameters. By considering any of the existing systems and by changing the p.d.f of failure rate of each element, we can drive different values and compare the results with each other.
